**Hocce Hemisphaerium Australe Serenissimo Principi ac Domino, Dno. Iacobo,
Praegloriosissimi Poloniarum Regis . . . (and) Hocce Hemisphaerium Firmamenti
Sobiesciani Boreale, Diversis novis Asterismis, et quàm plurimis novis Stellis . . .
Invictissimo Iohanni III. Poloniarum Regi**

Stock#: 27934
Map Maker: Hevelius

Date: 1687
Place: Gdansk (Dantzig)
Color: Hand Colored
Condition: VG+
Size: 21 x 21 inches

Price: SOLD

Description:

Fine example of Johannes Hevelius's northern and southern celestial hemispheres, from his highly important *Firmamentum Sobiescianum sive Uranographia*.

This pair of star charts shows the northern and southern skies, with rich full color and stars heightened in gold. The Key in each of the title banners shows the 6 different sizes of the stars on each chart.

The Hevelius *Firmamentum* was the first star atlas to rival Bayer's *Uranometria* in accuracy, utility, innovation, and influence. Hevelius was perhaps the most active observational astronomer of the last half of the seventeenth century. His star atlas is notable for many reasons. It contains fifty-six large, exquisite, double-page engraved star maps, each based upon drawings by the famous Polish artist Andreas Stech, who was also living and working in Dantzig at the end of the 17th Century. The star positions for the charts were derived from Hevelius's own star catalog, based on his own observations, which was first published along with the atlas. It is unique among the Grand Atlases in choosing to depict the constellations as they would appear on a globe, that is, from the outside looking in, rather than from a geocentric point of view, as Bayer and most others adopted. So Aquila and Antinous swoop down to the right, rather than to the left as in Bayer.

Johannes Hevelius (1611 - 1687) was a Protestant councilor and mayor of Danzig, in the Polish-Lithuanian Commonwealth. As an astronomer he gained a reputation as "the founder of lunar topography" and described ten new constellations, seven of which are still recognized by astronomers.

In 1641, Hevelius built an observatory on the roofs of his three connected houses, equipping it with

splendid instruments, including ultimately a large Keplerian telescope, with a wood and wire tube he constructed himself. This may have been the longest "tubed" telescope before the advent of the tubeless aerial telescope.

This private observatory was visited by Polish Queen Marie Louise Gonzaga on 29 January 1660, and in 1678 by Polish King John III Sobieski. In May 1679 the young Englishman Edmund Halley visited him as emissary of the Royal Society. Since 1664 Hevelius had been its first German fellow. Małgorzata Czerniakowska writes that "Jan Heweliusz was the first Pole to be inducted into the Royal Society in London. This important event took place on 19th March 1664." [6]

Halley had been instructed by Robert Hooke and John Flamsteed to persuade Hevelius to use telescopes for his measurements, yet Hevelius demonstrated that he could do well with only quadrant and alidade. He is thus considered the last astronomer to do major work without the use of a telescope.

Hevelius made observations of sunspots, 1642-1645, devoted four years to charting the lunar surface, discovered the Moon's libration in longitude, and published his results in *Selenographia, sive Lunae descriptio* (1647), a work which entitles him to be called "the founder of lunar topography."

He discovered four comets, in 1652, 1661 (probably Ikeya-Zhang), 1672 and 1677. These discoveries led to his thesis that such bodies revolve around the Sun in parabolic paths.

In late 1683, in commemoration of the victory of Christian forces led by Polish King John III Sobieski at the Battle of Vienna, he invented and named the constellation Scutum Sobiescianum (Sobieski's Shield), now called Scutum. This constellation first occurred publicly in his star atlas *Firmamentum Sobiescianum*, that was printed in his own house at lavish expense, and he himself engraved many of the printing plates.
